(Preface)

3.0 Introduction
3.1 Agency Roles
  3.1.1 Overview
  3.1.2 Local, State, and Federal Agencies
    - Local Public Health Agencies
    - State Public Health Agencies
    - State Agencies - Healthcare Facility Survey and Licensing
    - State Agencies - Provider Licensing
    - Federal Agencies - Centers for Disease Control and Prevention (CDC)
    - Federal Agencies - Food and Drug Administration (FDA)
  3.1.3 Healthcare Facilities
  3.1.4 Other Agencies and Partners
    - Professional Member Organizations
    - Tribal Entities and Indian Health Service (IHS)
    - Law Enforcement

3.2 Outbreak Response Team
3.2 Overview
3.2.1 Roles of Team Members
   Team Leader
   Epidemiologists
   Infection Preventionists
   Laboratorians
   Additional Team Members

3.2.2 Outbreak Response Team Model Practices
   Outbreak Response Unit
   Additional Support
   Outbreak Response Plans and Protocols
   Training for the Team

3.3 Resources
3.3.1 Equipment and Supplies
3.3.2 Outbreak Investigation Documents and Toolkits
3.3.3 Reference Materials
3.3.4 Tracking Time and Resources

3.4 Records Management
3.4.1 Overview
3.4.2 Records Management Model Practices
   Information Collection and Sharing
   Data Management and Investigation Tracking

3.5 Communication

3.6 Escalation
3.6.1 Overview
3.6.2 When to Ask for Help
3.6.3 How to Obtain Help

3.7 Incident Command System

3.8 Other Aspects of Preparation
3.8.1 Legal Preparedness and Authority
3.8.2 Ethics
3.8.3 Privacy
3.8.4 Permissions and Approvals

3.9 Planning for Recovery and Follow-Up
3.9.1 Overview
3.9.2 Recovery and Follow-Up Model Practices

PREFACE

Preparations ahead of an outbreak lay the groundwork for future actions taken during the outbreak response. Activities that prepare public health agencies to respond to outbreaks of healthcare-associated infections (HAIs) or antimicrobial resistance (AR) include developing the capacity to rapidly collect and analyze large amounts of information, take rapid action to stop transmission, and communicate with many partners that have a stake in HAI/AR outbreak prevention and response.
2. 
3. 

3.0 Introduction

Adequate preparation before an outbreak allows public health to take a systematic approach to HAI/AR outbreak detection and response, accelerating evaluation and minimizing response time. This chapter lays out essential preparations before an outbreak occurs, and describes the roles, resources, processes, and relationships that should be in place before an outbreak is detected. Although most activities in this chapter are directed toward public health agencies, other agencies, partners, and healthcare facilities can also use the information as a guide to understand their roles and interactions with public health. Prior to an outbreak, public health agencies should 1) engage with entities that may become partners in outbreak response, 2) understand the roles of various organizations during an outbreak, 3) develop scalable and flexible plans for all aspects of outbreak response, including the potential for incorporating the incident command system (ICS) when needed, 4) establish processes for records management and data analysis, and 5) assemble resources and tools that can be quickly accessed and used during a response.

AGENCY ROLES

3.1 Agency Roles

3.1.1 Overview

Prior to an outbreak, public health agencies, healthcare facilities, and partner organizations should have a clear understanding of their anticipated roles and responsibilities. This section describes roles and responsibilities of those charged with outbreak detection and response, including reporting, implementation of control measures, and ongoing monitoring until the outbreak has ceased. Since states have organized their governmental public health systems in different ways, the relative roles of local and state health departments will vary. In states where governance is centralized, responsibility for conducting outbreak investigations rests primarily with the state health departments. Conversely, in jurisdictions where governance is decentralized (“home rule” states), this responsibility may rest primarily with the local health department. Developing an understanding of individual agencies’ responsibilities and establishing strong working relationships is one of the most important preparation activities for any public health agency.

3.1.2 Local, State, and Federal Agencies

3.1.2.1 Local Public Health Agencies

Extensive knowledge of local healthcare networks, providers, and facilities possessed by local public health agencies places them in a position to actively engage partners across the continuum of care prior to an outbreak occurring. Local public health agencies can develop engaged partnerships through activities such as routine surveillance of reportable conditions;
bi-directional communication with healthcare organizations; attending, presenting at, and hosting meetings and educational events involving healthcare facilities and organizations; and including evaluation of potential for HAI/AR outbreaks in annual risk assessments. The capacity of local public health agencies varies considerably, with populations served varying from small, rural communities to large, metropolitan areas. Local public health agencies, along with state public health agencies, have roles and responsibilities as described below; when resources are limited, local public health agencies should obtain support from state public health agencies as necessary. In some jurisdictions (for example, those with centralized governance structures), the state public health agency might fulfill these roles.

Planning for outbreaks:
An understanding of endemic rates of disease can be helpful when planning for outbreak response. Public health agencies should establish methods for routine monitoring of baseline rates of HAIs, AR organisms, and other pathogens most commonly associated with outbreaks. Local epidemiology varies across jurisdictions, and understanding local trends is necessary to determine when an outbreak might be occurring. Personnel who are responsible for performing surveillance should be trained to recognize scenarios that might indicate an outbreak. They should understand levels of urgency and know whom to contact when an outbreak is suspected. Local public health agencies should understand local laboratory capacity and where to obtain advanced laboratory services, which might be needed to confirm outbreaks. Public health agencies should plan to engage in enhanced assessment and monitoring of infection prevention measures during an outbreak response until it is known that the outbreak has ceased, and effectiveness of control measures has been assured.

Roles and Responsibilities:
Roles and responsibilities for local public health agencies include conducting surveillance, ensuring reporting of outbreaks by facilities within their jurisdiction, receiving and evaluating suspected outbreak reports, providing recommendations to healthcare facilities to halt an outbreak, and notifying the public and media when warranted. Public health agencies detect HAIs, AR and other healthcare-associated pathogens through surveillance, either at the local or state level, and identify outbreaks via surveillance or receipt of outbreak reports. Local public health agencies also have a more granular view of the local population and may recognize characteristics, such as global travel patterns, that place some healthcare settings at increased risk of outbreaks. Local public health agencies may also recognize community transmission of pathogens that increase the opportunity for outbreaks within healthcare settings. Local public health agencies should maintain a list of contacts at healthcare facilities and should have a redundant system to notify them of public health concerns and regularly disseminate information about local patterns of illnesses that might increase the opportunity for HAI/AR transmission in healthcare settings. Public health agencies also have the role of providing general advice to the public in their jurisdiction. Depending on resources, a local public health agency also might perform advanced laboratory testing.

Resources:
Resources of a local public health agency vary by agency, but can include expertise in epidemiologic investigation, infection control, local healthcare provider outreach and health education. The local or state public health agency might serve as the coordinating agency during an outbreak investigation. However, the local public health agency has unique, in-depth knowledge of their local population, community, and healthcare facilities and organizations that is critical to leverage during outbreak investigation and response.
State public health agencies generally have broader situational awareness of HAIs, AR and other healthcare-associated pathogens in their state. Often HAI and AR pathogen surveillance is mandated at the state level, which in turn provides information to local jurisdictions and other partners. Typically, much of this surveillance activity, as well healthcare outbreak response and HAI/AR prevention, is coordinated or conducted under the auspices of the state health department’s HAI/AR Program. Most HAI/AR Programs have multidisciplinary HAI advisory groups which include members who bring extensive healthcare expertise, provide input on state HAI/AR action plans, and offer consultative advice to the state HAI/AR program. State HAI/AR action plans typically include outbreak detection and response activities, reflecting findings from infection control assessments conducted at healthcare facilities and lessons learned from previous outbreak investigations. State public health agencies strive to develop engaged partnerships with organizations that facilitate information sharing at the state and federal level, including organizations listed below, to support outbreak detection and response. State public health agencies might advise local public health agencies during a single jurisdictional outbreak or might take a coordinating role if the local public health agency does not have jurisdiction, lacks resources, or requests this. Multi-facility and multi-jurisdictional HAI/AR outbreaks are typically led by state public health agencies.

**Planning for outbreaks:**
State public health agencies monitor baseline rates of HAIs, AR and other healthcare-associated pathogens to understand baseline rates of transmission and local epidemiologic trends. Similar to local public health agencies, personnel who are responsible for performing surveillance should recognize scenarios that might indicate an outbreak. They should understand levels of urgency and know whom to contact when an outbreak is suspected. The state public health agency, working with the state public health laboratory, CDC, or other partners, has the ability to coordinate advanced laboratory services during outbreaks of AR pathogens and when other specialized testing is needed; it is important to maintain knowledge of which labs are available to perform advanced testing and how to interact with those laboratories to rapidly obtain testing. Public health agencies should plan to assess and ensure effectiveness of infection control measures implemented as part of an outbreak response. State public health agencies should plan in advance for notification, as appropriate, of other agencies, healthcare facilities, and the public.

**Roles and Responsibilities:**
Roles and responsibilities for state public health agencies are similar to local public health agencies, including conducting surveillance, ensuring reporting of suspected outbreaks by facilities, receiving and evaluating outbreak reports, providing recommendations to healthcare facilities to halt an outbreak, notifying the public and media when warranted, and facilitating advanced laboratory testing. State public health agencies also set policy for HAI and AR pathogen reporting, which facilitates detection of HAIs and AR pathogens through surveillance. State public health agencies might have more capacity than local public health agencies to detect clusters or outbreaks using surveillance data. State public agencies also have an important role in providing health advisories and prevention messaging to the public throughout the state. Often state public health agencies have more resources than local public health agencies and actively support local agencies; ideally this will include provision of training as part of preparation for outbreaks. Multi-facility and multi-jurisdictional outbreaks, outbreaks involving contaminated products where distribution is typically broader
than a local jurisdiction, and more complex outbreaks are more often investigated by state public health agencies; the Centers for Disease Control and Prevention (CDC) typically is the coordinating agency for multi-state outbreaks. The state public health agency has the role of ensuring communication among federal, state, and local partners during the investigation.

**Resources:**
State public health agencies have expertise in epidemiologic investigation, infection control, laboratory testing, and health education, as well as other more specialized expertise (e.g., clinical, pharmacy, antimicrobial stewardship). State public health agencies often have more resources to respond to outbreaks than local public health agencies; clear and frequent communication between state and local public health agencies, as well as with the healthcare provider community and other partners, fosters effective healthcare outbreak response.

### 3.1.2.3 State Agencies - Healthcare Facility Survey and Licensing

The role of the state survey agency includes overseeing state-level healthcare facility licensing requirements and Medicare certifications. To accomplish this, state survey agency personnel conduct surveys (inspections) of many types of healthcare facilities to assess adherence with the minimum health and safety standards established by the Centers for Medicare & Medicaid Services (CMS), as well as any state-specific criteria. The state survey agency might become actively involved in an outbreak response (for example, when regulatory assistance is deemed necessary to assure compliance with infection control requirements).

State public health agencies should have knowledge of policies and procedures for bi-directional sharing of information with the state survey agency both routinely and during an outbreak. Beginning in 2016, CMS issued expanded guidance requiring accrediting organizations and state survey agencies to report serious infection control breaches to the relevant state health department. Conversely, state public health agencies should establish thresholds for the notification of the state survey agency when outbreaks are being investigated. Including regulatory partners in outbreak response training can help clarify roles and enhance legal preparedness during an outbreak, including identifying the conditions or criteria that might warrant joint investigations between the state public health agency and state survey agency.

### 3.1.2.4 State Agencies - Provider Licensing

The role of professional licensing agencies (e.g., medical, nursing, dental, pharmacy licensing boards) is to oversee licensing and credentialing of healthcare providers and other licensed professionals and ensure that competency requirements are met. State professional licensing agencies might get involved in an outbreak response when regulatory assistance is needed for situations that involved licensed healthcare providers in healthcare settings that are not licensed or Medicare-certified at the facility level, such as a typical doctor’s office or dental practice. Likewise, licensing boards may receive or investigate complaints involving patient infections that could signal an outbreak, warranting attention from public health agencies.

State public health agencies should have processes in place that address bi-directional sharing of information with professional licensing agencies when needed; thresholds and limitations for sharing information should be established in advance. During outbreaks involving licensed healthcare providers, it can be helpful to involve professional licensing agencies if egregious
practices are found or questions arise regarding score of practice, particularly when a healthcare facility is not operating as a state-licensed healthcare facility. Involvement of the professional licensing agency might be simply providing information, or it might rise to the level of a joint investigation. This situation is generally less common than those involving licensed healthcare facilities, and therefore it is important for state public health agencies to have appropriate contact information and processes for contacting professional licensing boards, sharing information, and conducting joint investigations when needed. As with state survey agencies, including regulatory partners in outbreak response training can help clarify roles and enhance legal preparedness during an outbreak, including identifying the conditions or criteria that might warrant joint investigations.

3.1.2.5 Federal Agencies - Centers for Disease Control and Prevention (CDC)

CDC works with public health agencies at the state and local levels, and other federal agencies, such as the U.S. Food and Drug Administration (FDA), to provide support during outbreak response as well as coordinate multi-state outbreak investigations. During some outbreak situations, CDC sends experts to work side-by-side with facility and state or local public health agency staff. For example, state health departments may contact CDC and request assistance through a process known as an Epi-Aid. Typically, these efforts include on-site assistance, laboratory support and additional consultation with experts at CDC headquarters. In addition to formal Epi-Aid investigations, CDC routinely provides consultation and laboratory assistance to healthcare facilities and health departments that are working to solve outbreaks or investigate infection control breaches and other adverse events.

Specific to HAI/AR surveillance, prevention and outbreak response, CDC has a very active role supporting state and local public health agencies. For example, HAI/AR Programs receive funding, technical assistance and direction from CDC as part of its Epidemiology and Laboratory Capacity for Prevention and Control of Emerging Infectious Diseases (ELC) Cooperative Agreement with health departments. CDC also has the role to directly advise members of the public about what they can do to protect themselves, provides recommendations to the medical and public health community about how to prevent future outbreaks, and works closely with policymakers, regulatory agencies and industry to learn how to prevent outbreaks.

3.1.2.6 Federal Agencies - Food and Drug Administration (FDA)

FDA regulates and monitors the safety drugs and medical devices. FDA conducts investigations of outbreaks suspected to be related to medical products. It is important that public health agencies and healthcare facilities notify FDA about products potentially implicated in outbreaks and that they do so early, even if the association is not yet clear. Healthcare facilities and providers can report suspected product issues to the FDA via MedWatch, a voluntary web-based adverse event reporting program found here: https://www.fda.gov/safety/medwatch-fda-safety-information-and-adverse-event-reporting-program. Public health agencies can report directly to a regional FDA contact; this helps ensure that preliminary investigation findings and MedWatch reports are received and acted on in a timely manner. Determining the regional FDA contact ahead of an outbreak can facilitate timely communication. To foster bi-directional communication, state public health agencies can establish an information sharing agreement with the FDA. This is regulated by 21 CFR 20.88 and allows FDA to share non-public information (NPI) when it is in the interest of
Confidential Commercial Information (CCI) about all commodities regulated by FDA may be disclosed when a 20.88 is in place.

3.1.3 Healthcare Facilities

A brief discussion of some of the aspects of healthcare facility planning and preparation for HAI/AR outbreaks follows, although a full review is outside the scope of this guidance.

Roles and Responsibilities:
Healthcare facilities have primary responsibility for ensuring the safety of the patients under their care, as well as employees and visitors. When an outbreak is suspected, facility staff have the responsibility to report the outbreak within the facility (typically to the infection preventionist or quality team). Additionally, the facility has the responsibility to immediately report all suspected or confirmed outbreaks to the local or state public health agency. Often the healthcare facility will begin the investigation at the same time the outbreak is reported to public health. Whereas the healthcare facility has responsibility for ensuring the safety of the patients within their facility, the public health agency has an overlapping responsibility to protect the public from disease transmission, including within healthcare facilities in their jurisdiction. It is critical that healthcare facilities and public health collaborate to detect and respond rapidly to suspected outbreaks, sentinel events, and serious infection control breaches.

Within a healthcare facility, there should be at least one person designated to oversee measures to prevent transmission of infections, including the detection of and response to outbreaks. In hospitals and larger healthcare facilities, this person is usually a credentialed infection preventionist (IP); the IP may be supported by a medical epidemiologist and other team members. The roles and responsibilities for this team include conducting surveillance, detecting clusters or suspected outbreaks, ensuring reporting of outbreaks internally and to public health, communicating with public health during the course of an outbreak investigation, performing investigations to understand the cause of an outbreak in collaboration with public health, implementing changes in infection prevention practices to halt an outbreak, notifying patients and media when warranted, and performing laboratory testing in associated laboratories.

Planning for outbreaks:
Healthcare facilities should develop systems to ensure that there are adequate personnel to oversee implementation and monitor adherence to control measures in response to an outbreak. The facility IP should have completed competency-based training related to outbreak prevention and response (e.g., adhering to infection control measures such as transmission-based precautions, staff and patient cohorting practices, AR pathogen screening processes). The IP should establish processes for communicating with internal and external partners, including public health agencies.

Resources:
Resources within a healthcare facility to detect and respond to an outbreak vary greatly depending on the type of healthcare facility and the availability of staff with infection prevention expertise. Facilities with extensive resources and expertise in outbreak investigations may require little direct support from public health. Conversely, those lacking resources or expertise will be largely dependent on public health agencies to perform primary investigative functions. Regardless, every healthcare facility has unique, in-depth knowledge
of their facility that is critical during outbreak investigation and response. Public health agencies should be prepared to work collaboratively with healthcare facilities during an outbreak response. Similarly, healthcare facilities should be prepared to assist public health with the investigation including gathering information needed during the investigation and implementing disease control measures.

3.1.4 Other Agencies and Partners

Additional federal, state, territorial, tribal, local, and partner organizations might become involved in healthcare outbreak responses. It is important to think through in advance of an outbreak response all of the stakeholders and partners that might need to be involved or informed. Selected partners are described here in more detail, and abbreviated information about other partners is listed in Table 3.1. Table 3.2 details partners to consider including based on the type of outbreak or event.

3.1.4.1 Professional Member Organizations

Although not typically involved in outbreak detection and response directly, member organizations such as the local and national chapters of the American Professionals for Infection Control and Epidemiology (APIC), the Society for Healthcare Epidemiology of America (SHEA), and Infectious Disease Society of America (IDSA), as well as organizations representing medical, surgical, dental, nursing and other types of specialized healthcare professionals, can be valuable partners when public health needs to communicate to targeted groups and in understanding the local healthcare landscape. National organizations that represent healthcare facility types, such as the American Hospital Association (AHA) and American Health Care Association (ACHA) can be helpful partners to engage for messaging and coordination at the national level. These organizations also have local chapters in some jurisdictions; forming relationships with local chapters, such as the state hospital association, healthcare association, and healthcare professional or quality improvement organizations, can improve outbreak reporting and also help with communication to healthcare partners during an outbreak or during a time of increased transmission of a particular infectious disease. Developing relationships with these organizations helps ensure collaboration without overlap, so that organizations and agencies can mutually support outbreak response as well as general prevention and quality improvement efforts.

3.1.4.2 Tribal Entities and Indian Health Service (IHS)

Tribal governments generally have complete sovereignty and autonomy over reservation lands. Nontribal groups can join an investigation only at the tribe’s request. Investigations of outbreaks may be led by tribal health staff, Indian Health Service (IHS), or state health departments. Typically, public health and IHS can implement investigation measures and control only with the authorization of the tribal government.³

Healthcare organizations operated on tribal lands have a variety of configurations. Many healthcare facilities within tribal nations are autonomous and not bound by regulations that are applicable to other healthcare settings. Some facilities are owned by tribes and operated by IHS, a federal agency within the United States Department of Health and Human Services (HHS); other facilities are run entirely or in part by a tribal corporation that is independent of IHS. Additional information about IHS can be found in Table 3.1. Engaging tribal entities as partners requires awareness of the local healthcare structure and types of services offered.
State public health agencies should develop an understanding of the structure of healthcare facilities operated by tribal entities within the state. Local healthcare providers may have the most extensive knowledge of care patterns within tribal nations and the local public health agency in some cases might be the most effective agency for engaging tribal partners.

### 3.1.4.3 Law Enforcement

Under circumstances where criminal activity is suspected, appropriate law enforcement personnel should be notified. This might include situations where an outbreak investigation identifies persons who are suspected of committing fraud or providing medical care without appropriate credentials or persons who have stolen or tampered with controlled substances or other medications. For more information on drug diversion investigations, see the CSTE Drug Diversion Toolkit: [https://www.cste.org/general/custom.asp?page=Drug-Diversion-Toolkit](https://www.cste.org/general/custom.asp?page=Drug-Diversion-Toolkit). The law enforcement agency to be notified depends on the scenario; public health agencies should consider notifying local law enforcement, state law enforcement, and federal law enforcement depending on the circumstances. For example, medication tampering or other aspects of drug diversion might require notification of local law enforcement based on healthcare facility jurisdiction, state law enforcement, the Drug Enforcement Administration (DEA), and the FDA Office of Criminal Investigations. Public health agencies should maintain awareness of law enforcement reporting requirements; a contact list of law enforcement agencies can be developed in advance.

*State and local laws differ, and additional notifications may be applicable depending on laws and situation. Public health agencies should be prepared by understanding reporting requirements prior to an outbreak.

---

OUTBREAK RESPONSE TEAM

3.2 Outbreak Response Team

3.2.1 Overview

Prior to an outbreak, it is helpful for a public health agency to establish who will respond when an HAI/AR outbreak is detected; this is the outbreak response team. At its most basic level, an outbreak response team might consist of a single epidemiologist; larger or more complex events might need several staff including a more senior medical epidemiologist, an
infection preventionist, and other personnel with specialized expertise. A scalable response might require the staff involved in outbreak response to adapt to different roles during the investigation. Personnel designated as part of an outbreak response team should receive ongoing training in outbreak investigation and response. Roles and responsibilities for each team member should be clear and assigned early. Although public health agencies might designate roles in protocol documents and assign individuals to fill each role as the team is assembled at the beginning of a response, these roles should be flexible throughout the course of an outbreak investigation, and team members might fill more than one role.

3.2.2 Roles of Team Members

An entire outbreak response likely involves multiple entities (e.g., public health agency[ies], healthcare facility[ies]), each with their own response team. The overall coordinating agency might serve as a traditional lead or might act as a facilitator and convener. Regardless of which agency is in the lead, each team must appreciate the importance of considering multiple points of view across the various entities involved in the response.

Public health team members, their roles, and their primary responsibilities are described in this section. The purpose is to make it easy for public health agencies to quickly assign roles to team members and ensure key tasks are covered; however, responsibilities can be modified and transferred among team members as needed.

Consider designating a single point of contact for the public health team to communicate with other involved entities. The point of contact can be any team member, but consideration should be given to keeping the point of contact consistent throughout the investigation. Points of contact should have excellent communication skills and experience working in or with healthcare facilities.

3.2.2.1 Team Leader

During any response to a suspected outbreak, a team leader should be designated. In small outbreaks one epidemiologist might be sufficient to respond, but as soon as additional team members are added it is helpful to have a clear team lead. During multi-agency responses, it is similarly helpful to designate an overall lead, or coordinating, agency. The team leader at the coordinating agency might have the primary role of facilitator and convener, with other entities having their own team leads for their jurisdiction or facility. The team leader should make a concerted effort to appreciate the roles and expertise of their team and the members of teams working across other entities. The team leader sets the tone for the investigation and should be an individual who can maintain a calm demeanor during stressful situations.

Responsibilities:
Responsibilities of the team leader include: overall organization; setting priorities; leading meetings and conference calls including preparing clear agendas; coordinating all activities associated with the investigation; assigning roles and tasks to team members; modification of team roles and requesting additional staff when needed; coordinating messaging to other involved agencies, communication staff, and the outbreak response team; ensuring open communication among entities including with agency decision-makers; ensuring each team member and involved agency has needed information.

3.2.2.2 Epidemiologists
Epidemiologists usually have a central role in healthcare outbreak investigations. One or more epidemiologists may be needed to support the outbreak response team with sound epidemiologic approaches, ranging from descriptive epidemiology to complex analytic methods, to help determine the possible modes and sources of transmission and rapidly implement control measures.

**Responsibilities:**
Epidemiologists identify cases; develop case definitions; develop hypotheses and strategies to test them; obtain information about the cases and other patients via interviews, medical record reviews, and observations; perform descriptive analyses using collected data; plan epidemiologic studies; analyze investigation data using statistical analyses; present results to make interpretations; coordinate testing of specimens and samples; coordinate with other team members.

### 3.2.2.3 Infection Preventionists

HAI/AR outbreaks are unique in that infection control breaches of some kind are often the cause of or contributors to an outbreak. Infection preventionists (often referred to as IPs) have specific skills and training related to the prevention of transmission of infections in the healthcare setting. Infection preventionists are adept at assessing care practices and the environment of care; many IPs bring clinical experience and can contribute additional knowledge and context during an investigation.

**Responsibilities:**
An infection preventionist obtains and interprets information about the healthcare facility and the cases related to infection prevention practices; reviews and interprets policies and procedures; performs observations on-site to identify infection control gaps or breaches; provides infection control recommendations to the team and the healthcare facility to stop disease transmission; provides additional clinical context during the course of the investigation.

### 3.2.2.4 Laboratorians

Laboratorians provide expertise and advice related to the performance of laboratory testing. Laboratorians may also contribute specialized knowledge related to environmental reservoirs of HAI/AR pathogens. It is best practice for laboratorians to attend team meetings and be included in overall communications, not limited solely to laboratory aspects of the investigation. Excellent communication ensures that epidemiologists understand laboratory testing, and laboratorians are kept informed about the epidemiologic investigation.

**Responsibilities:**
Laboratorians advise the outbreak team on appropriate laboratory testing methods, including collection, handling, storage, and transport of clinical or environmental specimens; perform testing on clinical specimens; analyze environmental samples when obtained; interpret and report results; communicate laboratory testing methods and results; maintain chain of custody when required.

### 3.2.2.5 Additional Team Members
Administrative staff: Planning efforts should include support personnel to make phone calls, answer inquiries from concerned members of the public, perform data entry and assist with information management, and other administrative work.

Statistician: A statistician should be added to the team when advanced epidemiologic methods are employed requiring additional analytic skills. Some public health agencies might not have a statistician available. Consider requesting help from other agencies when additional statistical help is needed.

Public information officer: Public information officers (often referred to as “PIOs”) and communications experts should be involved early as a part of the outbreak response team when it is anticipated that the outbreak might be large enough to gain media attention, when communication assistance is needed among agencies, when developing messaging, such as for facilities or the public, or if other communication needs occur.

Legal support: Similar to public information officers, legal staff should be involved early as a part of the outbreak response team when it is anticipated that legal questions might arise. Legal staff can help with interpreting public health authority and when interacting with legal staff in other agencies and healthcare facilities.

Emergency preparedness: When a response to an outbreak or infection control breach might require large amounts of agency resources, when media attention might occur, or when establishing an incident command system (ICS) is being considered, public health agencies should consider involving emergency preparedness staff. Emergency preparedness staff can provide expertise in emergency response and ICS, as well as additional logistical support with resource requests (e.g., staffing or supplies).

3.2.3 Outbreak Response Team Model Practices

3.2.3.1 Outbreak Response Unit

Entities that routinely respond to healthcare outbreaks should establish a team that can be dedicated to that purpose. Ideally, outbreak response team members will be skilled in outbreak response and have knowledge of healthcare settings. Team members might have other responsibilities when outbreaks are not occurring, particularly at smaller agencies. Having a dedicated team allows for team members to gain experience working with each other and ensures consistency across investigations.

3.2.3.2 Additional Support

In large-scale events, it might be necessary to expand the outbreak team to have additional support with medical record reviews or interviews of patients, or other tasks such as data entry. Preparations to identify additional persons to assist with these tasks in advance can help the investigation proceed rapidly without taxing agency resources. Additional persons to be identified could include staff within other areas of an agency (some might have medical record review experience, or experience interviewing patients) or from other organizations (e.g., medical students, residents and fellows, public health students) who might have minimal levels of expertise. Inclusion of trainees in outbreak response can be beneficial for the team, helping with staffing and resource limitations, while also providing valuable
experience for the trainee. Develop just-in-time training for these additional support staff and provide directed training to allow for rapid incorporation of these staff into the team.

Public health agencies should identify possible sources of expertise to assist the outbreak response team when these are not internally available. Part of planning includes identification of gaps in expertise within the agency and identification of other entities that might have this expertise; often this might be at the state health department or CDC. Building relationships with a variety of healthcare facility and community partners can be an advantage when additional expertise is needed beyond the capacity of public health, particularly in areas not typically found within public health agencies, such as respiratory therapy, industrial hygiene, pharmacy, to name a few.

### 3.2.3.3 Outbreak Response Plans and Protocols

Outbreak response plans should be scalable, adaptable, and flexible so that they can be implemented when the outbreak is limited to a few cases, but rapidly expanded if the scope of the outbreak broadens. The plans should be flexible so that they can be used in any healthcare setting or in any unit, including specialized units, within facilities. It is helpful to have general outbreak response plans as well as pathogen/condition-specific response protocols for the types of outbreaks that are seen frequently. Established plans and protocols will allow for rapid response, support for less-experienced team members, and consistency across similar outbreaks. Plans can include contact lists (outbreak response team members, people within the agency to inform, outside agency contact lists, contact lists for additional support team members), steps to follow during an outbreak, scientific publications and other key reference texts, draft agendas for meetings and conference calls, draft emails for situational updates, medical record review forms, interview forms, on-site facility infection control assessment tools, laboratory testing information, and any other pieces that are common across outbreaks. Additional information about assembling documents and toolkits for healthcare outbreak response are described below in Section 3.3 Resources.

### 3.2.3.4 Training for the Team

Didactic and operational training for the team should be provided for all personnel who may be tasked with responding to an outbreak on a regular basis. Consider training on agency protocols, specific subjects (e.g., pathogens seen routinely, healthcare settings commonly worked with, infection control practices), and general outbreak response. Since healthcare outbreak response is specialized, public health staff responding to outbreaks should have training or experience in healthcare settings and understand the roles of healthcare facility staff, in particular infection preventionists. Consider shadowing opportunities within facilities when available and internal training sessions for staff who have never worked in a healthcare setting given by those who have. Staff unfamiliar with outbreak response in healthcare settings can be paired with more experienced and knowledgeable staff members when needed to provide on-the-job training. Specific just-in-time training can also be conducted when a new situation is encountered, or when adding team members with less experience in outbreak response. Training in ICS can also be helpful; ICS is discussed later in this chapter. Additional training is available for public health staff from a variety of resources; examples are listed in Box 3.1.
Conducting simulated exercises is another way to prepare for outbreak response. Exercises may be discussion-based or operations-based. Examples of discussion-based exercises include seminars, workshops, tabletops, and games simulating operations, many of which can be found online. Operations-based exercises include drills, functional exercises, and full-scale exercises. Regional training conducted with multiple agencies can help identify problems that might arise during outbreaks involving multiple entities.

RESOURCES

3.3 Resources

Part of preparing for the investigation of an HAI/AR outbreak is assembling the necessary resources—supplies, equipment, and personnel—to support the outbreak response team and ensure that everything needed in the investigation and response is readily available. This section describes resources that can be assembled prior to an outbreak. Personnel resource needs were discussed in the previous section. These lists of equipment, supplies, documents, and reference materials will help public health agencies identify resources in preparation for outbreak investigation; outbreak training should include methods to get resources specific to an outbreak as needed during the investigation.

3.3.1 Equipment and Supplies

List of equipment and supplies to consider in preparation for an outbreak response:
- Communication equipment: Consider the capability and equipment for conference calls and online meeting platforms that can support large numbers of users.
- Electronic equipment: Computers including laptops for fieldwork as well as needed software (e.g., data entry, statistical) should be available in advance, and portable

Box 3.1 Selected Training Resources

- Infection control training through CDC can be found at the following links:
  - CDC/STRIVE Infection Control Training: [www.cdc.gov/infectioncontrol/training/strive.html](http://www.cdc.gov/infectioncontrol/training/strive.html)
  - Project Firstline: [www.cdc.gov/infectioncontrol/projectfirstline/index.html](http://www.cdc.gov/infectioncontrol/projectfirstline/index.html)
  - Infection prevention training for nursing homes and assisted living facilities: [www.cdc.gov/longtermcare/training.html](http://www.cdc.gov/longtermcare/training.html)
- SHEA/CDC Outbreak Response Training Program (ORTP) can be found at [www.ortp.shea-online.org](http://www.ortp.shea-online.org).
- Healthcare epidemiology trainings offered by the Society for Healthcare Epidemiology of America (SHEA) can be found at learningce.shea-online.org.
- Infection prevention training resources offered by the Association for Professionals in Infection Control and Epidemiology (APIC) can be found at [https://apic.org/education-and-events/online-learning](https://apic.org/education-and-events/online-learning).
- Manufacturers of medical devices sometimes offer free or low-cost online or in-person training in device-specific reprocessing and infection prevention measures, such as online courses related to endoscope reprocessing.
printers can be considered. Consider needs for secure internet access; a secure personal hotspot can be helpful.

- Data storage and transportation devices: An encrypted portable data storage device (e.g., encrypted thumb drive) can help facilitate secure information sharing of electronic files too large to be emailed.
- Photography: It can be helpful to take photos during a field investigation. Ideally, personal cell phones should not be used. Be aware of your agency’s policy for taking photographs or videos during an outbreak. In general, avoid including people in photos unless permission is obtained; consult with the healthcare facility about applicable policies. If photographing the environment of care, ensure that photographs do not contain identifying information. Educate personnel about policies for taking, storing, and sharing photographs or videos.
- Laboratory supplies: Consider what will be needed depending on the specimens to be collected, including appropriate specimen collection materials and containers and transport materials (e.g., coolers and ice packs). Ensure appropriate shipping materials are available when needed. Prior to collecting samples, consultation with laboratory experts at the public health laboratory is advised. Environmental sampling should only be considered under specific conditions; Chapters 5 and 6 discuss additional considerations for environmental testing.
- Specialized instruments for the assessment of the environment of care, such as:
  - Ultraviolet gel and flashlight to be used in evaluation of environmental cleaning;
  - Flutter strips, smoke tubes, or velocimeters for evaluating positive or negative air flow;
  - Moisture meters to detect moisture in dry wall following exposure to water leaks.

Many acute care facilities have these instruments available, but public health agencies might find these items useful if assessing the environment of care in other healthcare settings.

3.3.2 Outbreak Investigation Documents and Toolkits

As noted above in Section 3.2.3 Response Team Model Practices, forms, information sheets, tools, plans and protocols can be created in preparation for outbreak response and modified as needed for specific situations. Public health agencies should consider developing specific guidance and protocols for outbreak response, including pathogen-specific protocols for common outbreaks, that take into account national guidelines but might be more specific for the jurisdiction based on local epidemiology. Information sheets, sample patient letters and any other materials intended for dissemination to the public should be easy to read and understand, with clear instructions for ease of implementation. Public health agencies can develop tools in advance that healthcare facilities can use to report outbreaks and respond to informational needs from public health agencies. Communication protocols can also be developed ahead of an outbreak that assist the team understand when to involve communication teams and leadership, and how to notify external partners, patients, and the public.

Outbreak investigation documents to consider in preparation for an outbreak response include:

- Outbreak intake forms, which might be general or disease-specific;
• Laboratory test requisition forms;
• Standardized outbreak line lists or database to collect case data;
• Forms for the assessment of adherence to infection prevention and control measures (e.g., ICAR, TAP assessments);\textsuperscript{5,6}
• Patient interview forms;
• Staff interview forms;
• Medical record review forms;
• Facility maps;
• Timeline templates;
• Line-list templates and samples;
• Template emails for information gathering;
• Template meeting or conference call agendas;
• Template letters of recommendation that public health agencies can use when recommending interventions in writing to healthcare facilities, including infection control recommendations;
• Template letters to patients (e.g., for patient notifications);
• Templates for final outbreak reports and after-action reports;
• Talking points for common pathogens or outbreak types for possible media inquiries; and
• Patient information sheets.

3.3.3 Reference Materials

It is not possible to compile specific references for every outbreak that might be encountered. However, having some common reference materials on hand in advance of an outbreak can save the team time in responding. Reference materials to consider compiling in preparation for an outbreak response include:

• Published medical literature specific to commonly encountered outbreaks;
• CDC HAI prevention toolkits, found at www.cdc.gov/hai/prevent/prevention_tools.html;
• CDC HAI Outbreak Investigation Toolkit found at www.cdc.gov/hai/outbreaks/outbreaktoolkit.html;
• CDC and Healthcare Infection Control Practices Advisory Committee (HICPAC) infection control guidance documents found at www.cdc.gov/infectioncontrol/guidelines/index.html;
• Latest version of the American Public Health Association’s Control of Communicable Diseases Manual;\textsuperscript{7}
• Selected resources from federal regulatory agencies, found in Box 3.2;
• Lists of resources from outbreaks previously investigated by the agency.

3.3.4 Tracking Time and Resources

Public health agencies should consider tracking time and resources during anticipated large-scale investigations. When processes are set up in advance of a response, tracking staff time and resources can be implemented rapidly, providing valuable information for future outbreaks and resource allocation.
RECORDS MANAGEMENT

3.4 Records Management

3.4.1 Overview

A tremendous amount of information can be collected during an outbreak response. Information needs to be collected and managed systematically to allow for easy access, interpretation, and analysis.

3.4.2 Records Management Model Practices

3.4.2.1 Information Collection and Sharing

---

Box 3.2 Selected Resources from Federal Regulatory Agencies

**Centers for Medicare & Medicaid Services (CMS)**
- Conditions of Participation and Conditions for Coverage (health and safety standards including infection control) that health care organizations must meet in order to begin and continue participating in the Medicare and Medicaid programs: [www.cms.gov/Regulations-and-Guidance/Legislation/CFCsAndCoPs](http://www.cms.gov/Regulations-and-Guidance/Legislation/CFCsAndCoPs)

**Food and Drug Administration (FDA)**
- National Drug Code Directory: [www.fda.gov/drugs/informationondrugs/ucm142438.htm](http://www.fda.gov/drugs/informationondrugs/ucm142438.htm)

**Environmental Protection Agency (EPA)**
- Selected EPA-registered Disinfectants: [www.epa.gov/pesticide-registration/selected-epa-registered-disinfectants](http://www.epa.gov/pesticide-registration/selected-epa-registered-disinfectants)

**Occupational Safety and Health Administration (OSHA)**
Standardized data collection forms (paper or electronic) can help ensure that data are collected uniformly and systematically. If forms are not already developed ahead of an outbreak, forms should be developed prior to data collection. Standardized forms can be modified from those used in previous outbreak investigations. Types of data collection forms include medical record review forms, patient interview forms, and healthcare facility staff interview forms. Staff collecting data should be trained in the use of the forms to ensure data is collected in the same way across team members.

Forms, data, and information should be shared among team members in a secure manner. Methods for sharing information and types of information to be shared across agencies should ideally be determined prior to an outbreak. Public health agencies should be aware that each entity involved in an outbreak response might have their own policies and limitations around the methods for sharing information (e.g., via encrypted email, shared documents on a secure website, etc.), and it is best practice to have several options available for sharing information to allow for flexibility.

3.4.2.2 Data Management and Investigation Tracking

Standardized databases and line lists should be used to collate data during an outbreak. General databases and line list templates can be developed ahead of time, or standardized tools or tools used in previous outbreaks can be modified. Data should be entered as soon as possible to allow for rapid interpretation and analysis. Identify tools to analyze outbreak data (e.g., Epi Info, SAS, R) and have staff that are trained to use these tools. Ensure data are routinely backed up and kept in a secure environment.

Each investigation, whether it involves a detected cluster, suspected or confirmed outbreak, AR containment, infection control breach, or other sentinel event, should be tracked in an information management system or database. The investigation tracking system should be flexible to accommodate the various types of events and provide information to allow authorized users to:

- Summarize overall investigation findings
- Evaluate effectiveness of local reporting requirements;
- Inform prevention efforts by identifying facilities, settings, and issues that might benefit from proactive prevention;
- Inform prevention and response guidance and tools;
- Understand local resources needed for outbreak response.

A best practice for public health agencies and larger healthcare facilities or systems is to use an outbreak investigation tracking system. CORHA has developed a HAI/AR Outbreak Investigation and Response Tracking System and associated data dictionary for this purpose, available at: www.corha.org/resources/corha-hai-ar-outbreak-and-response-tracking-system/. HAI/AR Programs receive specific guidance on response tracking from CDC as part of the ELC Cooperative Agreement. Information that can be captured in this type of database includes: intake information (entity reporting, dates of interest, basic description of the situation), healthcare facility information, public health agency information, investigation information (dates of testing and onset, case definition, numbers and characteristics of cases, investigation methods, suspected source), on-site visits conducted, laboratory information, control measures implemented, and summary and conclusions.
COMMUNICATION

3.5 Communication

Effective communication is one of the most important elements for a successful outbreak investigation. It is essential that there be processes in place for communication among the outbreak response team members, between the team and leadership within the agency, among involved agencies, with the healthcare facility or facilities involved, and with the media, patients and the public. To make communication as smooth as possible, prepare in advance and consider the following:

- Establish communication best practices for your outbreak team; strive for daily email updates or calls, with responsibility for organizing this assigned to one team member, established at the start of the investigation.
- Take partners’ needs into account when sending external updates, including those of the involved facility, regarding frequency, level of information, and content (e.g., summaries of findings to date).
- Develop guidelines for when to involve public information officers and communication experts, emphasizing the need to involve them as early as possible.
- Designate an outbreak response team member as the point of contact for each communication pathway.
- Create and use contact lists for partners and personnel; in some cases, contact lists can be developed in advance.
- Have clear agendas during meetings and calls; develop template agendas and meeting invitations which include an agenda; follow up with meeting minutes and/or a summary of key action items.
- Do not under-estimate the importance of ongoing discussions during the investigation, either in-person or via conference calls. It is extremely helpful to have scheduled meetings (in-person or calls) during the investigation to make sure communication pathways are established and partners are kept up-to-date.
- Develop procedures for presentations and publications, including procedures for early discussions internally and with partners regarding leads for any reports, papers or other products.
- Establish mechanisms for obtaining input and opinions from leaders in other communicable disease disciplines, such as foodborne and vaccine-preventable diseases, who can provide useful ideas for how to approach communications during an outbreak investigation.
- Regular meetings across disciplines and among healthcare partners as part of preparation can aid outbreak response later.

ESCALATION

3.6 Escalation

3.6.1 Overview
The public health outbreak team should periodically assess the need for obtaining additional assistance and escalating the response. Internally, there should be a communication protocol in place that includes triggers for notifying leadership and involving additional expertise (e.g., communication, emergency response, legal).

Thresholds for escalation to another agency should be considered in advance. Conversations with leadership and other internal experts can be helpful ahead of a possible escalation, and should involve preparing and educating leadership about the general course of an HAI/AR outbreak response and discussing when an outbreak might involve outside agencies. Leadership should also be knowledgeable about CDC’s Epi-Aid request process. An Epi-Aid is an investigation of an urgent public health problem, such as infectious or non-communicable disease outbreaks, unexplained illnesses, or natural or manmade disasters. When a public health authority, usually the state epidemiologist, requests assistance from CDC, an Epi-Aid allows rapid, short-term (1-3 weeks), generally onsite, technical assistance by Epidemic Intelligence Service (EIS) officers and other CDC subject matter experts. The focus of an Epi-Aid investigation is to assist partners in making rapid, practical decisions for actions to prevent and control the public health problem.

3.6.2 When to Ask for Help

A cardinal rule for all HAI/AR outbreak response teams: Ask for help earlier rather than later. A seemingly small or local outbreak might signal a much larger problem. Preparations should include discussions internally regarding when the agency might ask for help from another agency.

Consider asking for help when:

- The pathogen is novel or is of high consequence, or transmission appears to occur by novel means;
- The scale of the outbreak seems likely to overwhelm agency resources;
- Initial remediation attempts fail;
- The outbreak is known or suspected to affect multiple counties, states, or countries or expands beyond the jurisdiction;
- Investigation points to a regulated or widely distributed medical product;
- The nature of the outbreak (e.g., agent, affected population, scale) or response is beyond the experience of agency staff;
- Specific technical support or expertise is needed; or
- Specialized laboratory services or support is needed.

3.6.3 How to Obtain Help

Knowledge of how to obtain help when needed is a key aspect of a public health agency’s preparation and planning for healthcare outbreak response. Healthcare facilities should be reminded of requirements and thresholds for reporting potential outbreaks as soon as the outbreak is suspected and to not wait for an outbreak to grow, in order that they may receive prompt assistance and to ensure adequate patient protections are promptly put in place. In general, public health agencies should begin escalation by requesting assistance from the public health agency at the next jurisdiction level (e.g., local public health agencies should contact the state, state public health agencies should contact CDC). State public health
agencies have communicable disease or HAI/AR programs that can be contacted directly; if unable to locate contact information directly, call the general agency number or the 24/7 on-call person for the agency. Public health agencies can contact CDC for technical assistance related to healthcare outbreak investigations at haioutbreak@cdc.gov, or at the CDC 24/7 emergency response number (800-CDC-INFO).

INCIDENT COMMAND SYSTEM (ICS)

3.7 Incident Command System (ICS)

The Incident Command System (ICS) was originally developed in the 1970s to coordinate activities to control wildfires and is a scalable structure which states may adapt to meet their needs during an outbreak, including within a single jurisdiction. The system has been expanded and integrated into the Federal Emergency Management Agency’s (FEMA) National Incident Management System (NIMS) to aid intra-agency and interagency coordination, especially during large-scale emergencies that involve multiple jurisdictions. The ICS features a clearly defined chain of command with common nomenclature for key management positions, defined management sections, and a modular organizational structure. ICS uses specifically defined emergency response function roles. Public health agencies at the local and state levels may use ICS as part of an all hazards plan to mitigate threats to health and safety. Federal agencies are required by executive order to use the ICS to address outbreaks that are considered public health emergencies so that all relevant federal agencies, as well as state and local governments, are appropriately coordinated and connected with communication and decision-making during emergencies. The CMS Emergency Preparedness Rule\textsuperscript{10} has mandated that 17 different types of healthcare organizations develop all hazards plans, listed in Box 3.3.

Most HAI/AR disease outbreak investigations do not require formal activation of ICS, but elements of ICS are frequently utilized in outbreaks. For larger investigations or investigations that might lead to media attention, early use of ICS can be beneficial by providing additional structure and support to the outbreak response team.
**Box 3.3 Types of Facilities Required by CMS to Develop Emergency Preparedness Plans**

1. Hospitals
2. Religious Nonmedical Health Care Institutions (RNHCIs)
3. Ambulatory Surgical Centers (ASCs)
4. Hospices
5. Psychiatric Residential Treatment Facilities (PRTFs)
6. All-Inclusive Care for the Elderly (PACE)
7. Transplant Centers
8. Long-Term Care (LTC) Facilities
9. Intermediate Care Facilities for Individuals with Intellectual Disabilities (ICF/IID)
10. Home Health Agencies (HHAs)
11. Comprehensive Outpatient Rehabilitation Facilities (CORFs)
12. Critical Access Hospitals (CAHs)
13. Clinics, Rehabilitation Agencies, and Public Health Agencies as Providers of Outpatient Physical Therapy and Speech-Language Pathology Services
14. Community Mental Health Centers (CMHCs)
15. Organ Procurement Organizations (OPOs)
16. Rural Health Clinics (RHCs) and Federally Qualified Health Centers (FQHCs)
17. End-Stage Renal Disease (ESRD) Facilities

**OTHER ASPECTS OF PREPARATION**

### 3.8 Other Aspects of Preparation

#### 3.8.1 Legal Preparedness and Authority

Agencies should understand their legal authority to conduct an outbreak investigation and steps that can legally be taken to halt an outbreak; all relevant laws related to disease surveillance, reporting including outbreaks, detection, investigation, and control activities should be understood in advance. Specific authority and the basis for that authority, particularly when working in healthcare facilities, varies among states and jurisdictions; staff involved in outbreak investigations should understand the authority of their specific agency. If there are legal agreements that need to be in place for information sharing across agencies, these should be identified and put into place ahead of an outbreak. The agency should have legal staff available to provide advice and to join the outbreak response team when needed.

#### 3.8.2 Ethics

Ethical dilemmas might arise during the course of investigations of outbreaks or infection control breaches, particularly regarding decisions about patient notification. When possible, public health agencies should consider in advance of an outbreak investigation what standards and conventions to apply and criteria for arranging consultations and obtaining guidance. Although it is not always possible to anticipate ethical questions in advance, agencies should consider establishing guidelines that might be considered in advance. For example, agencies can consider what questions might need to be addressed to make the decision to notify patients of an outbreak at a healthcare facility, or the decision to notify patients of possible risks of bloodborne pathogens following an infection control breach.
Public health agencies should be familiar with laws related to protecting the confidentiality of patients and healthcare facilities. Protocols similar to those used in the collection of routine surveillance data might guide records management protocols that are compliant with the Privacy Act, the Federal Information Security Modernization Act (FISMA) the Healthcare Insurance Portability and Accountability Act (HIPAA), and state laws. Plan to collect the minimum amount of data needed. The privacy rule allows healthcare entities to share protected information directly with public health agencies who are legally authorized to receive reports for the purpose of controlling a disease, injury, or disability.\textsuperscript{11}

Methods aimed at maintaining the confidentiality of information collected during the outbreak should be instituted and adhered to consistently. Examples of methods to maintain confidentiality include: assigning a unique identifier to patients (such as when transporting forms with medical information, or when sharing information with agencies that do not need identifiers), encrypting emails when confidential information is shared between agencies, and limiting the identifiers collected to the extent possible. Identifiers include direct identifiers (such as name, date of birth, and address) and indirect identifiers (such as dates of admission and discharge).\textsuperscript{12}

Protection or disclosure of the name of a healthcare facility depends on state laws. In general, when there is a public health need to share to protect patients and the public, consideration should be given to sharing the name of the healthcare facility.

### 3.8.4 Permissions and Approvals

The outbreak response team should consider if there are permissions and approvals that might need to be obtained within their agency or across agencies. Understanding the permissions and approvals needed ahead of an outbreak can reduce miscommunication and speed up response. Make sure there is an understanding with leadership within the agency of any permissions and approvals.

Public health agencies should explore options and approaches for accessing facility medical records in advance of outbreaks. Often access to an electronic system of health records takes time to acquire, and valuable time can be saved if members of the outbreak team already have access; this might already be in place due to surveillance activities. In some cases access might be given at the level of the health system. Gaining access to facility electronic medical records can be challenging but worth the initial effort in advance of, or very early in, an outbreak investigation.

### PLANNING FOR RECOVERY AND FOLLOW-UP

#### 3.9 Planning for Recovery and Follow-Up

##### 3.9.1 Overview

Public health agencies should establish processes for completing an outbreak investigation, ensuring gap mitigation is maintained, and capturing lessons learned for applying them to
future outbreaks. See Chapter 5 for additional details. When the recovery and follow-up are planned ahead of an outbreak, information related to these activities can be recorded during the course of the outbreak investigation, saving time when investigations are wrapping up.

3.9.2 Recovery and Follow-Up Model Practices

Model practices to plan for recovery and follow-up include the following:

- Establish criteria at the start of an outbreak to determine actions that must happen, or endpoints that must be met, prior to de-escalating enhanced surveillance or prevention measures. As the outbreak evolves, these criteria can be modified. In some situations, general criteria can be established ahead of an outbreak.
- Ensure lessons learned are recorded throughout the outbreak investigation, and that these are available for informing and improving future outbreak response activities. Establish procedures for process improvement based on lessons learned.
- Identify final outbreak report templates and processes ahead of or early in the outbreak and consider populating information as the investigation progresses. This enhances recall and saves time at the end of an investigation.
- Consider after-action discussions following the investigation to identify successes, challenges, and any gaps that can be mitigated. Discussions should include agencies and the facilities, providers or other stakeholders that were involved in the response. It is often helpful to have discussions moderated by someone with expertise in facilitation. Preparation steps can include template after action reports, template agendas for after action meetings, and identification of facilitation experts.
CORHA Keys to Success

Key Planning and Preparation Steps

Resources

- Identify and train an outbreak response team. Develop plans for surge capacity and completion of other routine tasks during the outbreak investigation.
- Establish relationships among agencies and healthcare facilities most likely to be involved in outbreak responses ahead of an outbreak. (See CORHA Keys to Success: Developing relationships ahead of an outbreak.)
- Create standardized forms, templates, tools, databases, and protocols ahead of an outbreak. These can be modified as needed when an outbreak is detected.
- Ensure needed equipment and supplies are available ahead of an outbreak.
- Understand the capability for outbreak response among healthcare facilities within the jurisdiction, which will help with determining the level of response by public health when an outbreak occurs.

Processes Established Ahead of an Outbreak

- Develop clear processes and inform healthcare facilities of when and how to notify public health of an outbreak.
- Develop standardized processes for detection of an outbreak via surveillance and for receiving reports of outbreaks. Outbreak response team personnel should be familiar with these processes.
- Develop general and pathogen/specific outbreak response plans that are scalable, adaptable, and flexible.
- Establish plans that include frequent communication among and within agencies, including plans for regular communication (conference calls, meetings, emails) during the investigation. Template agendas and emails can be helpful to create ahead of time and modified as needed.
- Establish criteria to determine when to conclude an investigation, as well as processes to complete a final report. Establish processes to identify, review, and apply lessons learned at the end of a response, and to complete a team debriefing following investigation completion.
CORHA Keys to Success

Developing Relationships Prior to an Outbreak

An outbreak is not the time for first introductions. Partners within the public health and healthcare community should recognize the importance of mutually supporting capabilities during outbreak investigations.

Relationships

- Relationships among public health agencies, regulatory agencies (e.g., state survey agency, state licensing boards), member organizations, law enforcement agencies, and healthcare facilities should be developed at and across local, state, and federal levels.
- Public health and healthcare facility relationships can be developed by attendance of public health agency staff at local meetings such as the Association for Professionals in Infection Control and Epidemiology (APIC), holding educational events or conferences for healthcare facility partners, and attendance and presenting at facility-offered events such as grand rounds.
- Public health agencies should collaborate with local healthcare industry associations, such as the local hospital association, long-term care association, quality improvement organization, and professional societies. These organizations possess valuable knowledge of their stakeholders and can assist public health agencies in outreach efforts.
- Relationships are strengthened when public health agencies have established procedures for working with other agencies and organizations during outbreak response, and when public health staff understand the roles of their agency and partner agencies. Public health agencies can also develop tools to help healthcare facilities respond to public health requests during an outbreak response.
- Use local epidemiology, new guidance, and lessons learned from previous outbreak investigations to identify opportunities for outreach.
- Relationships with healthcare facilities are strengthened when public health understands and acknowledges the expertise of the healthcare facility. One way to accomplish this is to ask for assistance from facilities or providers with expertise in areas public health is working in.

Communication

- Procedures should be in place that describe general communication plans during an outbreak among involved partners. These procedures can be modified or specified in greater detail for individual outbreaks. Established communication plans can ensure clear communication is present from the initiation of an outbreak response.
- Plan for frequent communication among the outbreak response team and involved agencies; it is better to over-communicate than under-communicate. Prepared for communication using a variety of methods, including in-person or virtual meetings, conference calls, and email updates.
- Establishing methods and schedules for communication with facilities at the first stages of an investigation can help alleviate trying to communicate during busy schedules.
- Outbreak team members should practice excellent communication skills. Consider effective communication as one aspect of team member training in advance of an outbreak.

Flexibility

- Public health can assess the needs of healthcare facilities and provide services in advance (e.g., tools for outbreak response, advanced laboratory services); flexible collaboration at all stages of preparation will enhance relationships and facilitate a more nimble outbreak response if the investigation changes course.
- All involved agencies and healthcare facilities should understand that the outbreak investigation can change course quickly, and staff should remain flexible during an outbreak response. Preparation should not be so rigid that this need for flexibility is overlooked.
